### BACKGROUND

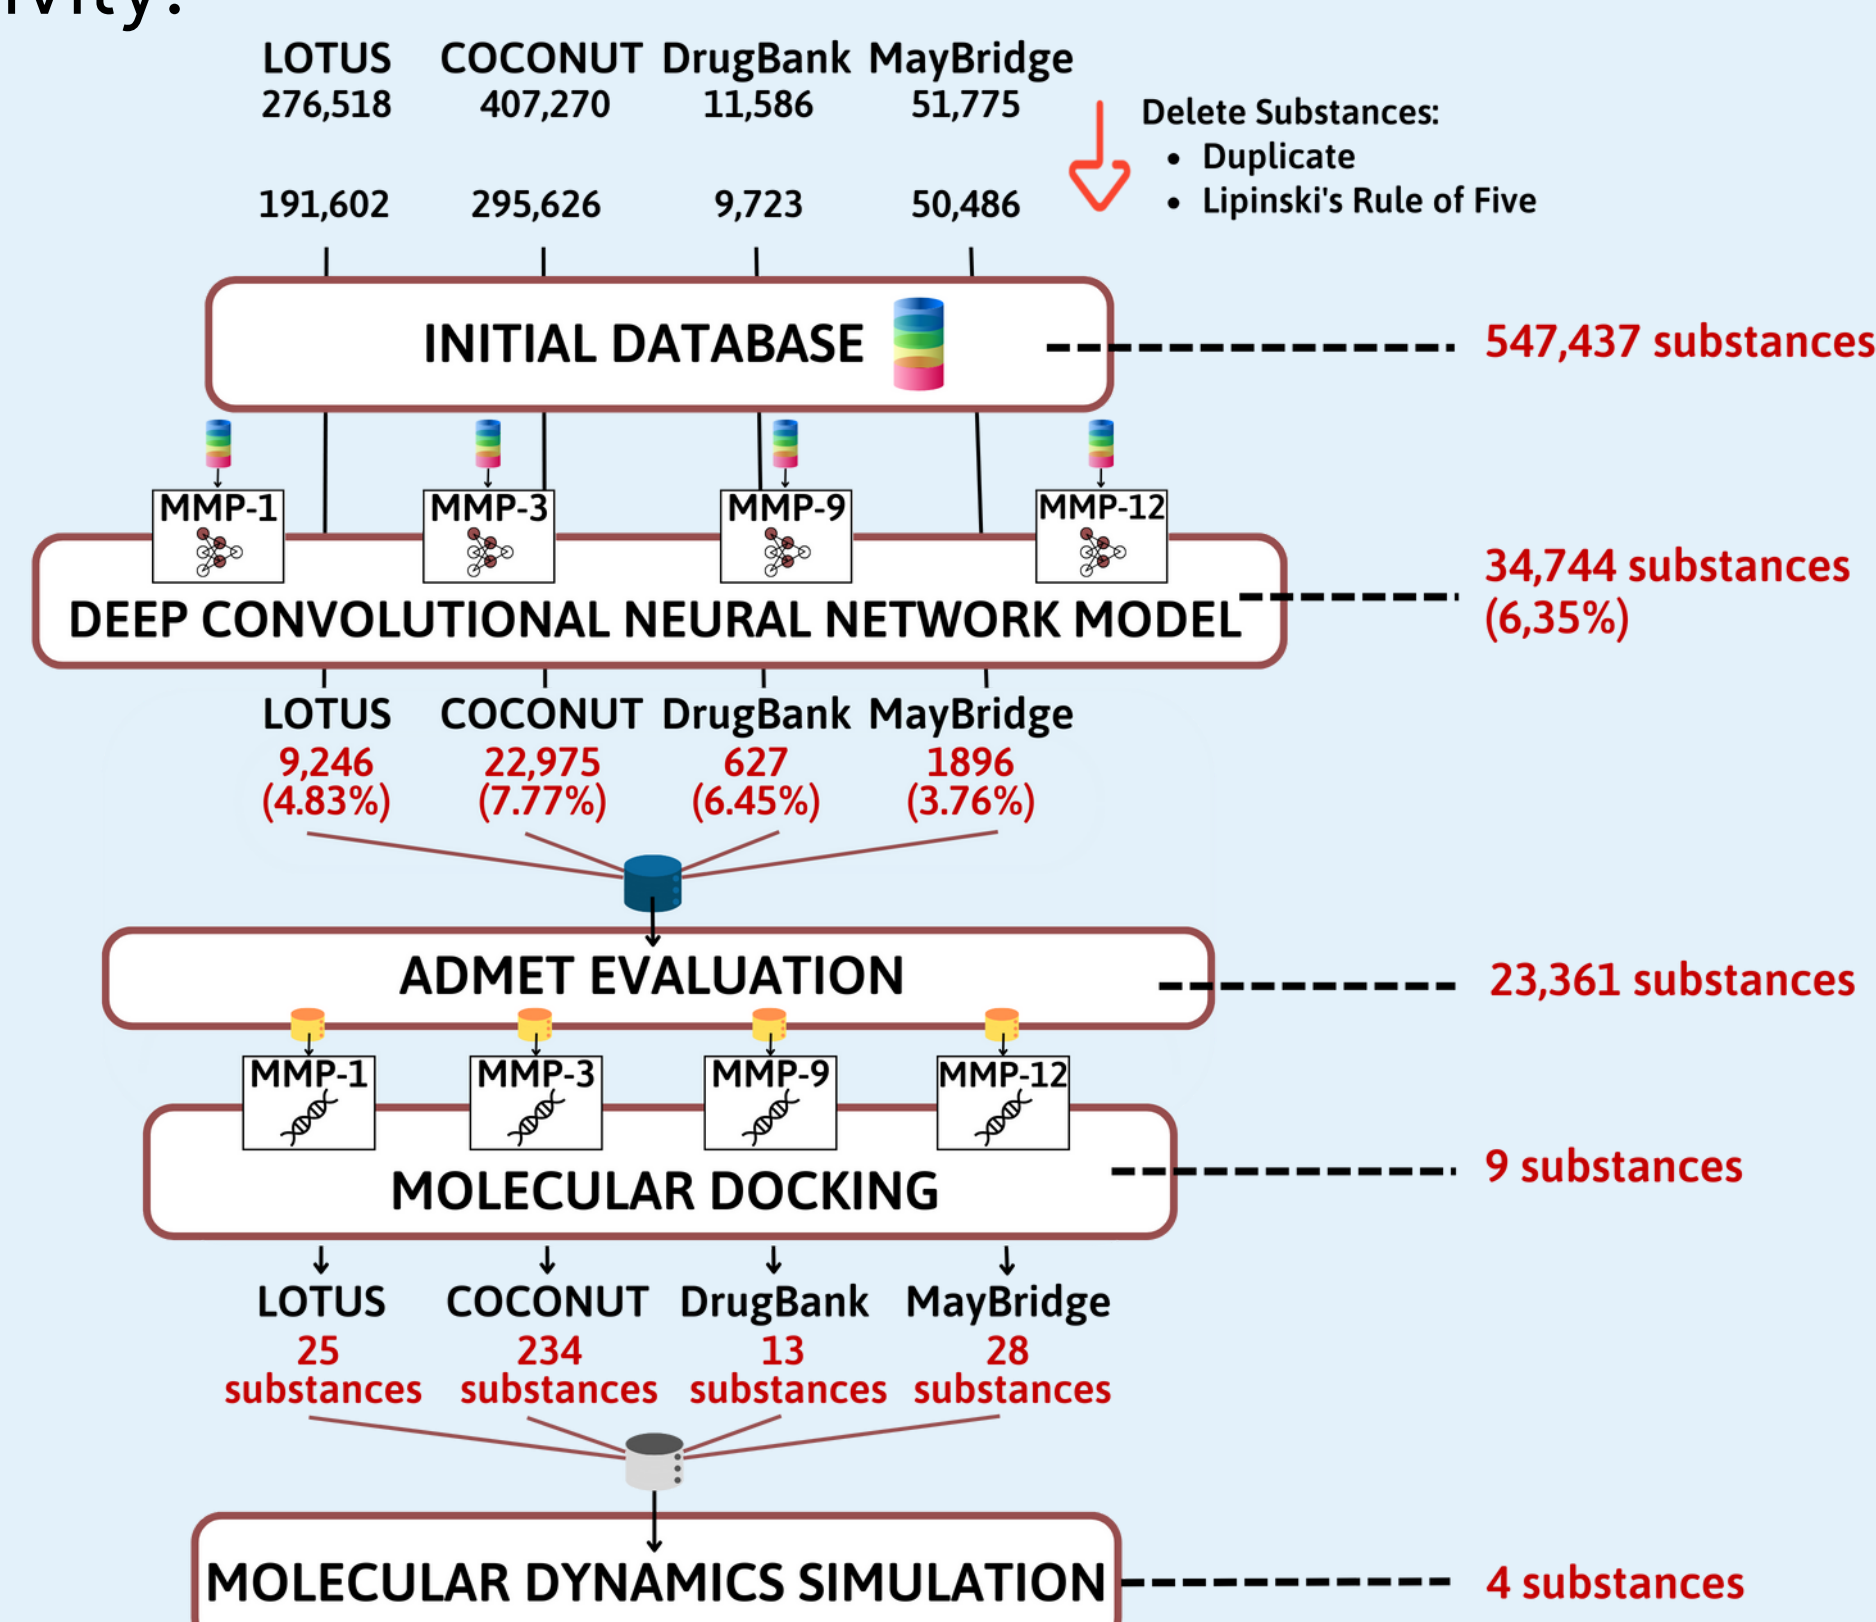

Skin aging due to the destruction of the extracellular matrix (ECM) system, which ensures the skin's structural integrity, is a significant concern for skin health. Four proteins in the matrix metalloproteinase family (MMPs) are overexpressed in skin aging and play an essential role in ECM hydrolysis, including MMP-1, MMP-3, MMP-9, and MMP-12. The study focuses on identifying broad-spectrum inhibitors for all four enzymes against skin aging.

### MATERIAL AND METHODS

### CONCLUSION

The study successfully developed a deep learning model and virtual screening process for four human MMPs, which are significant targets in skin aging. Over 500,000 compounds were screened through the entire process, and four potential broad-spectrum inhibitors of MMPs were found to show promise for skin anti-aging therapy. Four compounds required free binding energy results and in vitro testing in further research to further assess binding ability and confirm their bio-activity.
